**BICC – CPD 22/04/05**

# The Development of Foundation limit State Design

**Before World War II codes of practice for foundation engineering were used only in a small number of countries.**

**In 1956 Brinch Hansen used for the first time the words “limit design” in a geotechnical context.**

**Brinch linked the limit design concept closely to the concept of partial safety factors, and he introduced these two concepts in Danish foundation of engineering practice.**

# Basis Behind Eurocode 7

**The Limit state concept is today widely accepted as a basis for codes of practice in structural engineering. From the very beginning of the work on the Eurocodes it was a foregone conclusion that the Eurocodes should be written in the limit state design format and that partial factors of safety should be used.**

**Consequently it was decided that also those parts of the Eurocodes which will be dealing with geotechnical aspects of design should be written in the limit state format with the use of partial factors of safety**

**Geotechnical Categories & Geotechnical Risk Higher Categories satisfied by greater attention to the quality of the geotechnical investigations and the design**

**Table 1-Geotechnical Categories related to geotechnical hazard and vulnerability levels**

<b>Factors to be considered</b>	<b>Geotechnical Categories</b>		
	<b>GC1</b>	<b>GC2</b>	<b>GC3</b>
<b>Geotechnical hazards /vulnerability /risk</b>	<b>Low</b>	<b>Moderate</b>	<b>High</b>
<b>Ground conditions</b>	<b>Known from comparable experience to be straightforward. Not involving soft, loose or compressible soil, loose fill or sloping ground.</b>	<b>Ground conditions and properties can be determined from routine investigations and tests.</b>	<b>Unusual or exceptionally difficult ground conditions requiring non-routine investigations and tests.</b>
<b>Regional seismicity</b>	<b>Areas with no or very low earthquake hazard</b>	<b>Moderate earthquake hazard where seismic design code (EC8 Part V) may be used</b>	<b>Areas of high earthquake hazard</b>
<b>Surroundings</b>	<b>Negligible risk of damage to or from neighbouring structures or services and negligible risk for life</b>	<b>Possible risk of damage to neighbouring structures or services due, for example, to excavations or piling</b>	<b>High risk of damage to neighbouring structures or services</b>

**Table 1 (cont.)**

	<b>Geotechnical Categories</b>		
	<b>GC1</b>	<b>GC2</b>	<b>GC3</b>
<b>Expertise required</b>	<b>Person with appropriate comparable experience</b>	<b>Experienced qualified person – Civil Engineer</b>	<b>Experienced geotechnical specialist</b>
<b>Design procedures</b>	<b>Prescriptive measures and simplified design procedures e.g. design bearing pressures based on experience or published presumed bearing pressures. Stability of deformation calculations may not be necessary</b>	<b>Routine calculations for stability and deformations based on design procedures in EC7</b>	<b>More sophisticated analyses</b>
<b>Examples of structures</b>	<ul style="list-style-type: none"> <li>- <b>Simple 1 &amp; 2 storey structures and agricultural buildings having maximum design column load of 250kN and maximum design wall load of 100kN/m</b></li> <li>- <b>Retaining walls and excavation supports where ground level difference does not exceed 2m</b></li> </ul>	<p><b>Conventional:</b></p> <ul style="list-style-type: none"> <li>- <b>Spread and pile foundations</b></li> <li>- <b>Walls and other retaining structures</b></li> <li>- <b>Bridge piers and abutments</b></li> </ul> <p><b>Embankments and earthworks</b></p>	<ul style="list-style-type: none"> <li>- <b>Very large buildings</b></li> <li>- <b>Large bridges</b></li> <li>- <b>Deep excavations</b></li> <li>- <b>Embankments on soft ground</b></li> </ul> <p><b>Tunnels in soft or highly permeable ground</b></p>

# Ultimate Limite State (ULS) partial factors (persistant & transiet situations)

Table 2- Partial factors for ultimate limit states in persistent and transient situations

Parameter	Factor	Case A	Case B	Case C	Case C2	Case C3
<i>Partial load factors (<math>\gamma_F</math>)</i>		(UPL)	(STR)	(GEO)	(EQU)	(HYD)

# Serviceability Limit State Calculations (SLS)

Table 3 – Serviceability limits

Crack width mm	Degree of damage			Effect on structure and building use
	Dwelling	Commercial or public	Industrial	
> 0.1	Insignificant	Insignificant	Insignificant	None
0.1 to 0.3	Very slight	Very slight	Insignificant	none
0.3 to 1	Slight	Slight	Very slight	Aesthetic only
1 to 2	Slight to moderate	Slight to moderate	Very slight	Accelerated weathering to external features
2 to 5	Moderate	Moderate	Slight	Serviceability of the building will be affected, and towards the upper bound, stability may also be at risk
5 to 15	Moderate to severe	Moderate to severe	Moderate	
15 to 25	Severe to very severe	Moderate to severe	Moderate to severe	
>25	Very severe to dangerous	Severe to dangerous	Severe to dangerous	Increasing risk of structure becoming dangerous

# LIMIT STATE DESIGN – CHARACTERISTIC VALUE & DESIGN STRENGTH

**CHARACTERISTIC STRENGTH OF A MATERIAL** is the strength below which not more than 5% (or 1 in 20) samples will fail.

**CHARACTERISTIC STRENGTH =**  
MEAN VALUE – 1.64 X Standard Deviation

**DESIGN STRENGTH =**

CHARACTERISTIC STRENGTH       $f_y$   
MATERIAL FACTOR OF SAFETY       $\gamma_m$

## EXAMPLE:

Ten concrete cubes were prepared and tested by crushing in compression at 28 days. The following crushing strengths in N/mm<sup>2</sup> were obtained:

44.5 47.3 42.1 39.6 47.3 46.7 43.8 49.7 45.2 42.7

$$\text{Mean strength } x_m = \frac{448.9}{10} = \underline{44.9 \text{ N/mm}^2}$$

$$\text{Standard deviation} = \sqrt{[(x-x_m)^2/(n-1)]} = \sqrt{(80/9)}$$
$$= 2.98 \text{ N/mm}^2$$

$$\text{Characteristic strength} = 44.9 - (1.64 \times 2.98)$$
$$= 40.0 \text{ N/mm}^2$$

$$\text{Design strength} = \frac{40.0}{\gamma_m} = \frac{40.0}{1.5}$$
$$= 26.7 \text{ N/mm}^2$$

**Drawing Ref:**

**Date: 05/02**

**Ref**

**Calculations**

**Output**

The Characteristic Value of the angle of shearing resistance  $\phi'_{K}$  is required for a 10m depth of ground consisting of sand for which the following  $\phi'_{K}$  values were determined from 10 triaxial tests: 33°, 35°, 33.5°, 32.5°, 37.5°, 34.5°, 36.0°, 31.5°, 37°, 33.5°

To find the 95% confidence level, for soil properties, as only a small portion of the total volume involved in a design situation is tested, it is not possible to rely on Normal Distribution.

For a small sample size the Student t value for a 95% confidence level may be used to determine that  $X_K$  value, given by

$$X_K = X_m \left[ 1 - \frac{tV}{\sqrt{n}} \right] = X_m - \frac{t\sigma}{\sqrt{n}}$$

Some typical values of V for different soil properties given by

Soil Property	Range of typical V values	Recommended V Value if limited Test results available
$\tan\phi'$	0.05 – 0.15	0.10
$c'$	0.30 – 0.50	0.40
$c_u$	0.20 – 0.40	0.30
$m_v$	0.20 – 0.70	0.40
$\gamma$ (unit weight)	0.01 – 0.10	0

# Basic Cohesive Soil Founding Pressures

Shallow Foundation occurs when founding depth (D) is less than width (B)

$D/B < 1$  or when  $d < 3\text{m}$  (may not be applicable for rafts)

For undrained conditions, the base resistance  $q_B$  per unit area

Shallow foundation  $q_B = 5c_u + \gamma_s D$

Deep foundation  $q_B = 9c_u + \gamma_s D$

For the general soil type use the EC7 Brinch-Hansen equation.

# MALTESE CLAYS CHARACTERISTICS

Referring to Mr. A. Cassar A&CE, from various insitu tests carried out using SPT and laboratory tests on recovered samples, Maltese clays may be described as stiff to very stiff in its natural state, having an average C value of 100KN/m<sup>2</sup>, with a lower limit of 50 and an upper limit of 200.

Also the plastic limit (PL) of clay is given at 23%, with the liquid limit (LL) at 70% (Bonello 1988).

The plasticity index (PI) is thus given by  
 $PI = LL - PL = 47\%$

# **MALTESE CLAYS CHARACTERISTICS - continued**

**From the Casagrande plasticity chart this is classified as an inorganic clay of high plasticity.**

**From BS 8004 table 1, stiff clays have a presumed allowable bearing value of 150 to 300 kN/m<sup>2</sup>, whilst very stiff clays have values varying from 300 to 600 kN/m<sup>2</sup>.**

**For a PL at 23% and a high clay content, the shrinkage and swelling potential of Maltese clays is classified at high, usually showing cracks on drying.**

# Blue Clay Formation

Source: Saviour Scerri -geologist

# Blue Clay Formation

- Blue Clay has a high clay content
- Shrinkage due to desiccation is high and may reach 3m in depth
- Deep cracks are produced
- Clay loses all its cohesion
- Subsequent saturation produces clay slips

# Preparing A Clay Founding Layer

- In order to eliminate seasonal ground movement (heave or shrinkage) a min. foundation depth of 0.9m is suggested
- When constructing foundations in very dry weather, care must be taken to ensure superstructure loads are applied as soon as possible
- Foundations are to be placed at a sufficient distance from trees. To reduce above damage due to subsidence or heave, foundations should be placed at a distance away of  $0.5H$ , being the mature tree height.
- For trees such as the poplar, oak, elm, willow and eucalyptus the distance should be doubled to  $H$

	$BM \Rightarrow (123\text{kN/m}^2 - 9.9\text{kN/m}^2) \cdot 6^2 / 8$ $\Rightarrow 509\text{kN} \cdot \text{m/m}$ $\text{span/d} \Rightarrow 24 \quad d \Rightarrow 6000/24 \Rightarrow 250\text{mm}$ $y \Rightarrow M/bd^2 \cdot f_{ck} - \text{use concrete C25/30}$ $\Rightarrow 509 / 1.400^2 \cdot 25 \Rightarrow 0.127 \quad (\mu_{lim} \Rightarrow 0.167)$ $W \Rightarrow \frac{A_s \cdot f_{yk}}{bd \cdot f_{cu}} \Rightarrow 0.168 \quad (W_{lim} \Rightarrow 0.2336)$ $A_s \Rightarrow 3,652 \text{ mm}^2/\text{m}$ <p>The Shear Resistance with no axial load</p> $V_{Rd1} \Rightarrow \tau_{Rd} k (1.2 + 40 e_t) bd$ $\tau_{RD} \Rightarrow 0.3 \text{ N/mm}^2 \quad k \Rightarrow 1.6 - d \Rightarrow 1.2 \leq 1$ $e_t \Rightarrow 3,652 / 1.400 \Rightarrow 0.00091$ $V_{Rd1} \Rightarrow 0.3 \times 1.2 (1.2 + 40.0 \times 0.0091) \cdot 1.400$ $\Rightarrow 225 \text{ kN/m}$ $V \Rightarrow \frac{(123\text{kN/m}^2 - 9.9\text{kN/m}^2) (6\text{m} - 0.25\text{m})}{2}$ $\Rightarrow 311\text{kN/m} \text{ (shear links to be provided)}$	$h \Rightarrow 250 + 40 + 10$ $\Rightarrow 300\text{mm}$ $d \Rightarrow 450 - 40 - 10$ $\Rightarrow 400\text{mm}$

Project	Tas-Sellum Apartment Blk.	Job ref:
Part of Structure	Raft design to BS 8110	Sheet No. PO 4/2
Drawing ref.	Done by: DHC      Chkd By:	Date 03/05

Ref:	Calculations	Output
------	--------------	--------

$BM \Rightarrow 509kNm/m \times 1.45 / 1.4 \Rightarrow 527kNm/m$   
 $k \Rightarrow M/bd^2.f_{cu} \Rightarrow 527 / 1.400^2.30 \Rightarrow 0.11$   
 $a_1 \Rightarrow \bar{z} / d \Rightarrow 0.86 \bar{z} \Rightarrow 0.86 \times 400 \Rightarrow 344mm$   
 $A_s \Rightarrow M/(0.87f_y) \bar{z} \Rightarrow 527/(0.87 \times 460 \times 344) \Rightarrow 3,828mm^2/m$   
 $v \Rightarrow (123kN/m^2 - 9.9kN/m^2) \times \frac{1.45 \times (6m - 0.25m)}{1.4 \times 2}$   
 $\Rightarrow 322kN/m$   
 $v \Rightarrow 322 / 1.400 \Rightarrow 0.8N/mm^2$   
 $\ell \Rightarrow 3,828 / 1.400 \Rightarrow 0.96\%$   
 $v_c \Rightarrow 0.67N/mm^2$   
 so increase  $\ell$  to 1.75%       $V_c \Rightarrow 0.8N/mm^2$   
 $A_{s_{req}} \Rightarrow 7000mm^2/m$  (Y32 @ 115mm centreline)

**Commentary :-**

Thus EC2 is more economical on tensile steel (3,652mm<sup>2</sup>/m as against 3,828mm<sup>2</sup>/m), however, shear links are to be included as per EC2, whilst BS 8110 has the possibility of increasing steel area to 7,000mm<sup>2</sup>/m and providing no shear links.

# Constructing a Raft Foundation

- Raft foundations should be placed on fully compacted draining infill separated by a polythene sheet not exceeding 1.0m in depth. The raft and fully compacted fill tend to act compositely in resisting the heave forces. Heave movement is reduced by removing the most desiccated clay layer.
- For protection against the possibility of future tree planting producing damaging ground movement the bored pile foundation is more suitable. The upper part of the pile shaft in the clay desiccation zone should be sleeved to reduce uplift swelling forces
- Heaving pressures in clays may be up to  $200\text{KN/m}^2$

# Indirect Design Methods

This is the traditional method used in most countries. In this method calculations are carried out at characteristic stress levels (CP 2004 – table 1 enclosed) with unfactored load and ground parameters.

Although EC7 does not provide provision for this method, it is expected to be included in the revised version.

Foundations on rock applicable to this method, although Annex G of EC7 gives presumed bearing resistances dependant on the rocks compressive strength and discontinuity spacing.

# Foundation Settlement EC7 – Appendix F

Adjusted elasticity method  $s = pBf/E_m$  (cohesive & non-cohesive)

$p$  is elastic bearing pressure linearly distributed

$f$  is the settlement coefficient?

$E_m$  is the soil modulus of elasticity

Appendix H outlines structural deformation & foundation movement

# ALLOWABLE SETTLEMENTS & ROTATIONS

For normal structures with isolated foundations total settlements up to 50mm acceptable. A max relative rotation of 1/500 acceptable for most structures, given in EC7.

Other sources' max raft total settlement of clay up to 125mm with differential settlements of 45mm acceptable. For sand, total given at 50mm and differential at 30mm.

Isolated foundations max. deflection on clay given at 75mm (sand 50mm).

Brick buildings total settlement quoted at 75-100mm. Angular distortion of 1/300 also quoted.
